# 14 Programmable Gamma Reference Buffers with Four Static References for TFT-LCD Displays 

## General Description

The MAX9590 provides 14 programmable voltage references and four static voltage references for gamma correction in TFT-LCD displays. Two register banks are provided to store two sets of gamma reference values. Gamma values are programmed into the banks through the $\mathrm{I}^{2} \mathrm{C}$ interface and the outputs can switch between values in $0.5 \mu \mathrm{~s}$.
The 14 programmable reference voltages are divided evenly into seven upper and seven lower voltages for the upper and lower gamma curves of LCD column drivers.
Each gamma reference voltage has an 8-bit digital-toanalog converter (DAC) and isolation buffer associated with it to ensure stable operation. Therefore, the reference voltages remain stable without synchronizing to the LCD horizontal timing. In addition, each buffer is able to provide a high current that further ensures a stable voltage when critical levels and patterns are displayed.
The 14 programmable buffers wake up in the high-impedance state until the registers are programmed. This protects the LCD system from high transient currents during the startup phase.
The MAX9590 is available in a 38-pin TQFN package and is specified for operation over the $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ temperature range.

Applications
TFT-LCD Displays
Industrial Reference Voltage Generators

Ordering Information

| PART | TEMP RANGE | PIN-PACKAGE | PKG <br> CODE |
| :---: | :---: | :--- | :---: |
| MAX9590ETU+ | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | 38 TQFN-EP** <br> $(5 \mathrm{~mm} \times 7 \mathrm{~mm})$ | T3857-1 |

+Denotes lead-free package.
${ }^{* *} E P=$ Exposed paddle.

Features

- 14 Programmable Reference Voltages
- Four Static Reference Voltages
- Independent DACs with 8-Bit Resolution
- Two Register Banks for Two Sets of Gamma Values
- Fast Switching between Gamma Values
- 16.5V (max) Operating Voltage
- Output Swing within 150 mV of Rails
- Peak Current Greater than 200mA
- Output Channels Tri-Stated During Wake-Up

Block Diagram

## ABSOLUTE MAXIMUM RATINGS

| OUT_REFU_H, OUT_REFU_L, |  |
| :---: | :---: |
| Short-Circuit Duration |  |
| Any Output to AVDD or GND | us |
| Continuous Power Dissipation ( $\mathrm{T}_{\mathrm{A}}=+70^{\circ} \mathrm{C}$ ) |  |
| 38 -Pin TQFN (derate $26.3 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ above $+70^{\circ} \mathrm{C}$ ) | C) ..... 2195 mW |
| Operating Temperature Range ........................-40 | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| Junction Temperature | $+150^{\circ} \mathrm{C}$ |
| Storage Temperature Range ......................... -65 | $65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Lead Temperature (soldering, 10s) | $+300^{\circ} \mathrm{C}$ |

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## 14 Programmable Gamma Reference Buffers with Four Static References for TFT-LCD Displays

Typical Application Circuit

# 14 Programmable Gamma Reference Buffers with Four Static References for TFT-LCD Displays 

## Detailed Description

The MAX9590 provides 14 channels of programmable voltage references and four channels of static voltage references for gamma correction in TFT-LCD displays. Two register banks are provided to store two different sets of gamma reference values. Gamma values are programmed into the banks through the $I^{2} \mathrm{C}$ interface and the outputs can switch between values in $0.5 \mu \mathrm{~s}$.

## Output Buffers

The 14 programmable reference voltages are divided evenly into seven upper and seven lower voltages for the upper and lower gamma curves of LCD column drivers.
The seven upper voltages cover the range between REFU_L to REFU_H. The seven lower voltages cover the range of REFL_L to REFL_H.
Each gamma reference voltage has an 8-bit DAC and isolation buffer associated with it to ensure stable operation. Therefore, the reference voltages remain stable without synchronization to the LCD horizontal timing. In addition, each buffer is able to provide a high current that further ensures a stable voltage when critical levels and patterns are displayed.
Each of the MAX9590 output buffers hold the reference voltages stable while providing the ability to source and sink current (200mA) into a capacitive load such as LCD column drivers. When switching from Bank A to Bank B or vice versa, the outputs settle to within $\pm 0.5$ LSB in less than $0.5 \mu \mathrm{~s}$.

## 8-Bit DAC

Each voltage is generated by an 8 -bit DAC and programmed values are set through the $1^{2} \mathrm{C}$ interface. The input code data is used to set the output voltages of the MAX9590. See the $I^{2}$ C Compatibility section.
The ideal transfer function of the upper reference voltages is:
$V_{\text {OUT1 }}$ to $V_{\text {OUT2 }}=V_{\text {REFU_L }}+\frac{D}{255} \times\left(V_{\text {REFU_H }}-V_{\text {REFU_L }}\right)$
while the ideal transfer function of the lower reference voltages is:
$V_{\text {OUT8 }}$ to $V_{\text {OUT14 }}=V_{\text {REFL_L }}+\frac{D}{255} \times\left(V_{\text {REFL_H }}-V_{\text {REFL_L }}\right)$

$$
\begin{gathered}
\mathrm{D}=2^{7}(\mathrm{~B} 7)+2^{6}(\mathrm{~B} 6)+2^{5}(\mathrm{~B} 5)+2^{4}(\mathrm{~B} 4)+2^{3}(\mathrm{~B} 3) \\
+2^{2}(\mathrm{~B} 2)+2^{1}(\mathrm{~B} 1)+2^{0}(\mathrm{BO})
\end{gathered}
$$

$D$ is the decimal value of the input binary code. $B 7$ is the most significant bit of the data byte and is clocked in first.
Table 1 shows the ideal output voltage of VOUT1 and Vout14 with the following typical conditions:

$$
\begin{gathered}
V_{\text {REFU_H }}=14 \mathrm{~V}, \mathrm{~V}_{\text {REFU_L }}=9 \mathrm{~V}, \mathrm{~V}_{\text {REFL_H }}=6 \mathrm{~V}, \\
\text { and } \mathrm{V}_{\text {REFL_L }}=1 \mathrm{~V}
\end{gathered}
$$

## Table 1. Ideal Output Voltage with Typical Conditions

| BINARY <br> INPUT | DECIMAL <br> VALUE | VOUT1 <br> $\mathbf{( V )}$ | VoUT14 <br> (V) |
| :--- | :---: | :---: | :---: |
| 00000000 | 0 | 9.00 | 1.00 |
| 00000001 | 1 | 9.019 | 1.019 |
| 00000011 | 3 | 9.058 | 1.058 |
| 00000111 | 7 | 9.136 | 1.136 |
| 00001111 | 15 | 9.292 | 1.292 |
| 00011111 | 31 | 9.605 | 1.605 |
| 00111111 | 63 | 10.230 | 2.230 |
| 01111111 | 127 | 11.480 | 3.480 |
| 11111111 | 255 | 14.00 | 6.00 |

Register Banks
The MAX9590 features two register banks: Bank A and Bank B. The user can program one set of gamma values into Bank A while Bank B is being used to drive the LCD column drivers and vice versa.
Set BANK_SEL = 0 to select Bank A and set BANK_SEL = 1 to select Bank B. The gamma voltage transition from Bank A to Bank B and vice versa takes place in less than 500 ns. See the Register Address section for details on memory bank internal registers.

## Power-On Reset (POR)

The MAX9590 contains an integrated POR circuit that ensures all registers are reset to a zero state on power-up. Once DVDD rises above 1.5 V (typ), the POR circuit releases the registers for normal operation. Should the DVDD input drop to less than 1.5 V (typ), the POR is activated.
After a POR, the outputs (OUT1-OUT14) are in highimpedance mode until a minimum of two data bytes have been written to both Bank A and Bank B in any order.

# 14 Programmable Gamma Reference Buffers with Four Static References for TFT-LCD Displays 

## Thermal Shutdown

The MAX9590 features thermal-shutdown protection with temperature hysteresis. When the die temperature reaches $+160^{\circ} \mathrm{C}$, OUT1-OUT14 shut down. When the die cools down by $15^{\circ} \mathrm{C}$, the device turns on again. When in thermal shutdown, the amplifier outputs (OUT1-OUT14) are high impedance. The four static buffers remain active. When exiting thermal shutdown, the amplifier outputs return to the programmed output voltages.

## Serial Interface

The MAX9590 features an $I^{2} \mathrm{C}$-compatible, 2-wire serial interface consisting of a bidirectional serial data line (SDA) and a serial clock line (SCL). SDA and SCL facilitate bidirectional communication between the MAX9590 and the master at rates up to 400 kHz . Figure 1 shows the 2 -wire interface timing diagram. The MAX9590 is a transmit/receive slave-only device, relying upon a master to generate a clock signal. The master (typically a microcontroller) initiates data transfer on the bus and generates SCL.

A master device communicates with the MAX9590 by transmitting the correct slave ID followed by a command and/or data words. Each transmit sequence is framed with a START (S) or repeated START (Sr) condition and a STOP (P) condition.
The SDA driver is an open-drain output, requiring a pullup resistor to generate a logic-high voltage. Optional resistors in series with SDA and SCL (i.e. $300 \Omega$ ) protect the device inputs from high-voltage spikes on the bus lines. Series resistors also minimize crosstalk and undershoot of the bus signals.

Bit Transfer
Each SCL rising edge transfers one data bit. The data on SDA must remain stable during the high portion of the SCL clock pulse (Figure 2). Changes in SDA while SCL is high are read as control signals (see the START and STOP Conditions section). When the serial interface is inactive, SDA and SCL idle high.

Figure 1. 2-Wire Serial-Interface Timing Diagram

Figure 2. Bit Transfer

# 14 Programmable Gamma Reference Buffers with Four Static References for TFT-LCD Displays 

## START and STOP Conditions

A master device initiates communication by issuing a START condition which is a high-to-low transition on SDA with SCL high. A START condition from the master signals the beginning of a transmission to the MAX9590. The master terminates transmission by a STOP condition (see the Acknowledge Bit (ACK) and Not-Acknowledge Bit (NACK) section). A STOP condition is a low-to-high transition on SDA while SCL is high (Figure 3). The STOP condition frees the bus. If a repeated START condition is generated instead of a STOP condition, the bus remains active. When a STOP condition or incorrect slave ID is detected, the MAX9590 internally disconnects SCL from the serial interface until the next START or repeated START condition, minimizing digital noise and feedthrough.

## Early STOP Conditions

The MAX9590 recognizes a STOP condition at any point during transmission except when a STOP condition occurs in the same high pulse as a START condition (Figure 4). This condition is not a legal I2C format; at least one clock pulse must separate any START and STOP conditions. The MAX9590 discards any data received during a data transfer aborted by an early STOP condition.

Repeated START Conditions
A repeated START condition is used to indicate a change in direction of data flow (see the Register Mode Read Operation section). Repeated START may also be used when the bus master is writing to several ${ }^{12} \mathrm{C}$ devices and does not want to relinquish control of the bus. The MAX9590 serial interface supports continuous write operations with (or without) an Sr condition separating them.

## Acknowledge Bit (ACK) and Not-Acknowledge Bit (NACK)

Successful data transfers are acknowledged with an acknowledge bit (ACK) or a not-acknowledge bit (NACK). Both the master and the MAX9590 (slave) generate acknowledge bits. To generate an acknowledge, the receiving device must pull SDA low before the rising edge of the acknowledge-related clock pulse (ninth pulse) and keep it low during the high period of the clock pulse (Figure 5). If a master transmitter is involved in a data transfer, it must signal the end of data to the slave transmitter by not generating an acknowledge on the last byte that was clocked out of the slave. The slave transmitter must release the SDA to allow the master to generate a STOP or repeated START condition. Monitoring the acknowledge bits allows for detection of unsuccessful data transfers. An

Figure 3. START/STOP Conditions

Figure 4. Early STOP Conditions

Figure 5. Acknowledge and Not Acknowledge Bits

## 14 Programmable Gamma Reference Buffers with Four Static References for TFT-LCD Displays

unsuccessful data transfer happens if a receiving device is busy or if a system fault has occurred. In the event of an unsuccessful data transfer, the master should reattempt communication at a later time.
The MAX9590 generates an acknowledge when receiving an address or data by pulling SDA low during the ninth clock pulse. When transmitting data during a read, the MAX9590 does not drive SDA during the ninth clock pulse (i.e. the external pullups define the bus as a logic high) so that the receiver of the data can pull SDA low to acknowledge receipt of data. When the last byte of data is received by the master during a read, a not acknowledge is generated where the SDA line is not pulled low by the master receiver.

Slave ID A bus master initiates communication with a slave device by issuing a START condition followed by the 7-bit slave ID (Figure 6). When idle, the MAX9590 waits
for a START condition followed by its slave ID. The serial interface compares each slave ID bit by bit, allowing the interface to power down and disconnect from SCL immediately if an incorrect slave ID is detected. After recognizing a start condition followed by the correct slave ID, the MAX9590 is programmed to accept or send data. The LSB of the slave ID word is the Read/Write (R/W) bit. R/W indicates whether the master is writing to or reading from the MAX9590 (R/W $=0$ selects a write condition, $\mathrm{R} / \overline{\mathrm{W}}=1$ selects a read condition). After receiving the proper slave ID, the MAX9590 issues an ACK by pulling SDA low for one clock cycle.
The MAX9590 slave ID consists of five fixed bits B7...B3 (set to 11101) and two programmable bits B2 and B 1 . The most significant slave ID bit (B7) is transmitted first, followed by the remaining bits. The MAX9590 slave ID is determined by connecting AO to GND or DVDD or SCL or SDA. Table 2 shows the four possible slave IDs of the device.

Figure 6. Slave ID Byte Definition

Table 2. Slave ID Description

| A0 | B7 | B6 | B5 | B4 | B3 | B2 | B1 | B0 | WRITE ADDRESS <br> (Hex) | READ ADDRESS <br> (Hex) |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| GND | 1 | 1 | 1 | 0 | 1 | 0 | 0 | $R / \bar{W}$ | $0 \times E 8$ | $0 \times E 9$ |
| DVDD | 1 | 1 | 1 | 0 | 1 | 0 | 1 | $R / \bar{W}$ | $0 x E A$ | $0 \times E B$ |
| SCL | 1 | 1 | 1 | 0 | 1 | 1 | 0 | $R / \bar{W}$ | $0 x E C$ | $0 x E D$ |

# 14 Programmable Gamma Reference Buffers with Four Static References for TFT-LCD Displays 

## Register Address

The MAX9590 consists of two register banks A and B. Each register bank has 14 internal registers with addresses as shown in Table 3.

## Control Data Byte

Use the control data byte to configure the MAX9590. The MAX9590 control byte contains a write-designator bit (C1) and a read-designator bit (C2). The rest of the bits (C0 and C3-C7) are don't-care bits. The most significant bit (B7) is transmitted first, followed by the remaining bits. Table 4 shows the control data byte.

The write-designator bit (C1) determines to which bank to write. '0' corresponds to Bank A while '1' corresponds to Bank B. At POR, C1 is set to 0 . See Figures 7, 11, and 13 for more details.
The read-designator bit (C2) determines which bank to read from. A '0' corresponds to Bank A while a '1' corresponds to Bank B. At POR, C2 is set to 0. See Figures 7, 11, and 13 for more details.
After a POR, the outputs (OUT1-OUT14) are in highimpedance mode until a minimum of two data bytes have been written to both Bank $A$ and Bank $B$ in any order.

Table 3. Register Mapping

| REGISTER | HEXADECIMAL CODE | POWER-ON DEFAULT VALUES | REGISTER ADDRESS |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | R7 | R6 | R5 | R4 | R3 | R2 | R1 | R0 |

## Modes of Operation (Standard Mode (STD_REG = 1)) Standard Mode Write Operation

For the standard mode write operation, send the slave ID as the first byte followed by the control byte and then a burst of 14 data bytes. The control byte specifies the bank (to be written to or read from). Once the MAX9590 receives the control byte, the device transfers the control byte data into the control byte register. After this operation, the register address is set to A01 for Bank A or B01 for Bank B. The address gets automatically incremented from A01 (or B01) and the 14 data bytes are written to the corresponding register addresses until A14 (or B14) is reached. If more than 14 data bytes are written, the excess is ignored. Only data written up to A14 or B14 will be accepted. Data written
past A14 or B14 is ignored. Terminate the data transfer with a STOP condition. The standard mode write operation is shown in Figure 7.
The MAX9590's responses to burst-write operations for various scenarios are summarized in Table 5.

## Standard Mode Read Operation

The standard mode read operation can be performed on the same bank or on the second bank. If the read operation does not require a bank change, send the slave ID with an R/W bit of 1 . The register address is set internally to A01 (or B01) depending on the value of the previously written control byte. The control byte is not sent during a read operation unless a bank change is required. Read the 14 data bytes and then terminate the transmission using a STOP as shown in Figure 8.

Figure 7. Standard Mode Write Operation

## Table 5. Standard Mode Write Operation—Response to Burst Write

| SCENARIO | RESPONSE |
| :--- | :--- |
| Burst-write operation involving <br> more than 14 data bytes | The device writes data bytes into the corresponding register addresses in sequential order <br> starting with the first register address (A01 or B01). The device ignores the excess bytes after <br> register address A14 or B14. |
| Burst-write operation involving <br> less than 14 data bytes | The device writes data bytes into the corresponding register addresses in sequential order, <br> starting with the first register address (A01 or B01), until the specified number of data bytes <br> have been written. |

Figure 8. Standard Mode Read Operation

## 14 Programmable Gamma Reference Buffers with Four Static References for TFT-LCD Displays

If a read operation requires a bank change, transmit the slave ID with a R/W bit of ' 0 ' and send the control byte to change the bank. After a repeated START signal, the 14 bytes are read from the respective bank as shown in Figure 9.
The MAX9590's responses to burst-read operations for various scenarios are summarized in Table 6.

## Register Mode (STD_REG = 0)

Register Mode Write Operation
For the register mode single write operation, send the
slave ID, register address, and then data. For the register mode burst-write operation, send the slave ID, register address, and then the burst of data bytes. The address gets automatically incremented internally from the address specified and the data is written to the corresponding register addresses. If more than 14 data bytes are written, the excess is ignored. Only data written up to A14 or B14 is accepted. Data written past A14 or B14 is ignored.
Figure 10 shows a single/burst-write operation in the register mode.

Figure 9. Standard Mode Bank Change Read Operation
Table 6. Standard Mode Read Operation—Response to Burst Read

| SCENARIO | RESPONSE |
| :--- | :--- |
| Burst-read operation involving <br> more than 14 data bytes | The device reads the valid data bytes starting from A01 (or B01) till A14 (or B14). The rest of <br> the data bytes read are 0xFF (hexadecimal) indicating that those data are invalid. |
| Burst-read operation involving <br> less than 14 data bytes | The device reads data bytes from the corresponding register addresses in sequential order <br> starting with the first register address (A01 or B01) and stops after the specified number of data <br> bytes have been read. |

Figure 10. Register Mode (Single/Burst) Write Operation

## 14 Programmable Gamma Reference Buffers with Four Static References for TFT-LCD Displays

If a write operation requires a bank change, the byte sent after the slave ID is the control register's address ( $0 \times 00$ in the MAX9590) and data following this address is the control byte data to switch banks. After switching banks, execute a normal register mode write operation as shown in Figure 11.
The MAX9590's responses to burst-write operations for various scenarios are summarized in Table 7.

## Register Mode Read Operation

The read operation in the register mode is an ordinary ${ }^{2} \mathrm{C}$ read operation if the bank is not changed. Send the slave ID followed by the register address. The register address needs to be the location from which the data byte is to be read. Use a repeated START to change the direction of data transfer. Send the slave ID with an R/W bit of 1 to facilitate a read operation. Read the required number of data bytes and terminate the transfer. The register mode read operation is shown in Figure 12.

Figure 11. Register Mode Bank Change Write Operation
Table 7. Register Mode Write Operation—Response to Burst Write

| SCENARIO | RESPONSE |
| :--- | :---: |
| Burst-write operation involving more data bytes than valid register address locations <br> (A01-A14 or B01-B14). <br> Illustration 1: Burst-write operation involving more than 14 data bytes starting with register address A01. <br> Illustration 2: Burst-write operation involving more than 2 data bytes starting with register address A13. | The device ignores <br> excess bytes after <br> register address <br> A14 or B14. |

Figure 12. Register Mode Read Operation

## 14 Programmable Gamma Reference Buffers with Four Static References for TFT-LCD Displays

If a read operation requires a bank change, send the slave ID followed by the control register's address (0x00 in MAX9590) and then the control byte data to switch banks. After switching banks, execute a normal register mode read operation as shown in Figure 13
The MAX9590's responses to burst-read operations for various scenarios are summarized below in Table 8.

I2C Compatibility
The MAX9590 is compatible with existing ${ }^{2} \mathrm{C}$ systems. SCL and SDA are high-impedance inputs; SDA has an open-drain output that pulls the data line low during the ninth clock pulse. The communication protocol supports standard $I^{2} \mathrm{C} 8$-bit communications. The general call address is ignored, and CBUS formats are not supported. The devices' address is compatible with 7 -bit ${ }^{12} \mathrm{C}$ addressing protocol only. No 10-bit address formats are supported. Repeated START protocol is supported.

Figure 13. Register Mode Bank Change Read Operation
Table 8. Register Mode Read Operation—Response to Burst Read

| SCENARIO | RESPONSE |
| :--- | :--- |
| Burst-read operation involving <br> more than 14 data bytes | The device reads the valid data bytes starting from the specified register address until A14 (or <br> B14). After A14 (or B14), the rest of the data bytes read are 0xFF (hexadecimal) indicating that <br> those data are invalid. |
| Burst-read operation involving <br> less than 14 data bytes | The device reads data bytes from the corresponding register addresses in sequential order <br> starting with the specified register address and stops after the specified number of data bytes <br> has been read. |

## 14 Programmable Gamma Reference Buffers with Four Static References for TFT-LCD Displays

## Applications Information

## Power Dissipation

The maximum power dissipation is the sum of analog circuitry power dissipation, digital circuitry power dissipation, and power dissipation due to the load calculated using a maximum operating voltage of $A V_{D D}=$ 16.5 V and $\mathrm{DV}_{\mathrm{DD}}=5.5 \mathrm{~V}$.

Total Power Dissipation $=\mathrm{PD}($ analog $)+\mathrm{PD}$ (digital) + PD(load)
$P D($ analog $)=16.5 \mathrm{~V} \times 28 \mathrm{~mA}=462 \mathrm{~mW}$
$\mathrm{PD}($ digital $)=5.5 \mathrm{~V} \times 0.75 \mathrm{~mA}=4.13 \mathrm{~mW}$
Each output buffer supplies an average load current of 5 mA . The power dissipation per output buffer is therefore:
$5 \mathrm{~mA} \times 16.5 \mathrm{~V} / 2$ (average) $=41.25 \mathrm{~mW}$
The device has a total of 18 output buffers therefore:
$\mathrm{PD}($ load $)=41.25 \mathrm{~mW}$ per output buffer $\times 18$
buffers total $=742.5 \mathrm{~mW}$
$\mathrm{PD}($ total $)=462 \mathrm{~mW}+4.13 \mathrm{~mW}+742.5 \mathrm{~mW}=$ 1208.63 mW

There will also be AC switching power dissipation, but because of the low duty cycle and the fast transition times involved, this should be minimal.
The maximum power dissipation of the 38-pin TQFN package is 2195 mW with a derating factor of $26.5 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ above $+70^{\circ} \mathrm{C}$. Therefore, the maximum power dissipation of the 38-pin TQFN package at $+85^{\circ} \mathrm{C}$ is 1800 mW .

## Power Supplies and Bypass Capacitors

 The MAX9590 operates from a single +9 V to +16.5 V analog supply and $\mathrm{a}+2.7$ to +5.5 V digital supply. Bypass AVDD to GND with $0.1 \mu \mathrm{~F}$ and $10 \mu \mathrm{~F}$ capacitors in parallel. Use an extensive ground plane to ensure optimum performance. Bypass DVDD to GND with a $0.1 \mu \mathrm{~F}$ capacitor. Bypass CAP (pin 29) to GND with a $0.1 \mu \mathrm{~F}$ capacitor.Refer to the MAX9590 evaluation kit for a proven PC board layout.

Layout and Grounding
Solder the exposed paddle to a ground plane to provide a low thermal resistance to ground for heat dissipation. Do not route traces under these packages.
