#### **5.FUNCTION DESCRIPTIONS**

#### 5.1 Registers in VFD Controller

The VFD controller has two 8-bit registers, an instruction register (IR) and a data register (DR). IR stores instruction codes, such as display clear and cursor shift, and address information for DD-RAM and CG-RAM The IR can only be written from the host MPU.DR temporarily stores data to be written into DD-RAM or CG-RAM and temporarily stores data to be read from DD-RAM or CG-RAM. Data written into the DR from the MPU is automatically written into DD-RAM or CG-RAM by an internal operation. The DR is also used for data storage when reading data from DD-RAM or CG-RAM. When address information is written into the IR, data is read and then stored into the DR from DD-RAM or CG-RAM by internal operation. Data transfer between MPU is then completed when the MPU reads the DR. After the read, data in DD-RAM or CG-RAM at the next address is send to the DR for the next read from the MPU. By the register selector (RS) signal. These two registers can be selected (See Table-8).

																						Curs	or

- 2. CG-RAM address bits 0 to 2 designate the character the patter line position. The 8<sup>th</sup> line is the cursor position and its display is formed by a logical OR with the cursor. Maintain the 8<sup>th</sup> line If bit 4of the 8<sup>th</sup> line data is 1.1 bit will light up the cursor regardless of the cursor presence
- 3. Character pattern row positions correspond to CG-RAM data bits 0 to 4 (bit 4 being at the left )
- 4. As show Table-11 CG-RAM character patterns are selected when character code bits 4 to 7 are all 0. However, since character code bit 3 has no effect, the display example above can be selected by either character code 00H or 08H
- 5. 1 for CG-ram data corresponds display selection and 0 to non-selection."×" Indicates non-effect.

NAME	SPECIFICATION FOR APPROVAL		00	12/22

# 5.2 Interfacing to the MPU

This VFD module can interface in either two 4-bir operations or one 8-bit operation, thus allowing interfacing with 4-bit or 8-bit MPUs.

※ For 4-bit interface data, only four bus lines (DB4 to DB7) are used for transfer. When to use 4-bit parallel data transfer, DB0 to DB3 keep "H" or "L". The data transfer between the VFD module and the MPU is completed after the 4-bit data has been transferred before the four low order bits (for 8-bit operation. DB0 to DB3).

The busy flag (BF) are performed before transferring the higher 4 bits. BF checks are not required before transferring the lower 4 bits.

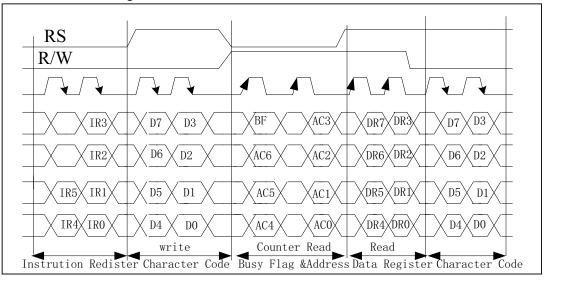

Fig 4-biti transfer Example (M68)

\*For 8-bit interface data, all eight bus lines (DB0 to DB7) are used.

## 5.3 Reset Function

5.3.1 Power-on reset

An internal reset circuit automatically initializes the module when the power is turn on. The following instructions are executed during the initialization.

- Display clear
   Fill the DD-RAM with 20H (Space Code)
- Set the address counter to 00H Set the address counter (ACC) to point DD-RAM.

5.3.2 Ex	ternal			

In order to use this function, a user must connect the soldering pad "JP1". When the soldering pad "JP1" is open-circuited, this function is not valid and when it is short-circuited, the third hole (pin #3) is used for external reset input. If low level signal longer than 500ns is input into the hole, reset function being same as power on reset is executed.

#### 5.4 Soldering Land Function

Some soldering lands are prepared on the rear side of PCB, to set operating mode of the display module. A soldering iron is required to short soldering lands.

Table-12 Soldering Land OPEN/SHORT Combination Table

Mode	IP2	IP3	IP4	IP5	IP6	IP7
Parallel (Motorola)	(Note 1)	open	shorted	open	shorted	open
Parallel (Intel)	(Note 1)	open	shorted	open	open	shorted
Serial	open	shorted	open	shorted	shorted	open

Note 1: JP2 shorted (open) enables (disables) external reset mode.

NAME

### 6. INSTRUCTIONS

#### 6.1 Outline

Only the instruction register (IR) and data register (DR) of the VFD controller can be controlled by the user's MPU. Before starting the internal operation of the controller, control information is temporarily stored into these registers to allow interfacing with various MPUs, which operate at different speeds, or various peripheral control devices. The internal operation of the controller is determined by signals sent from the MPU. These signals, which include register selection signal (RS), read/write signal (R/W), and the data bus (DB0 to DB7), make up the controller instructions (See Table-13). There are four categories of instructions that:

- designate controller functions, such as display format, data length, ect.
- Set internal RAM addresses
- Perform data transfer with internal RAM
- Perform miscellaneous functions

Normally instructions that perform data transfer with interval RAM are used the most.

However, auto-increment by 1 (or auto-decrement by 1) of internal RAM addresses after each data write can lighten the program load of the MPU. Since the display shift instruction can perform concurrently with display data write, the user can minimize system development time with maximum programming efficiency.

When an instruction is being executed for internal operation, no instruction other than the busy flag/address read instruction can be executed. Because the busy flag is set to 1 while an instruction is being executed, check it to make sure it is 0 before sending another instruction from the MPU.

Note: Be sure the controller is not in the busy state (BF=0) before sending an instruction from the MPU to the nodule. If an instruction is sent without checking the busy flag, the time between the first instruction and next instruction will take much longer than the instruction time itself. Refer to Table-13 for the list of each instruction execution time.

STANDARD	SPECIFICATION FOR APPROVAL	DOCUMENT NO.	REV.NO	PAGE
NAME	SPECIFICATION FOR AFFROVAL		00	20/22

This instruction

(1) Loads a new 7-bit address into the address counter (ACC).

(2) Sets the address counter (ACC) to point to the DD-RAM.

Once the "Set DD-RAM Address" instruction has been executed, the contents of the address counter (ACC) will be automatically modified after each access of DD-RAM, as selected by the "Entry Mode Set" instruction.

Table-16 Valid DD-RAM address Ranges

	Number of Character	Address Range
1 <sup>st</sup> line	40	00H to 27H
2 <sup>nd</sup> line	40	40H to 67H

#### 6.2.9 Read Busy Flag and Address

DB7	DB6 DB5	DB4	DB3	DB2	DB1	DB0
BF			ACC	2		

RS=0, R/W=1

Read busy flag and address reads the flag (BF) indicating that the system is now internally operating on a previously received instruction. If BF is 1, the internal operation is in progress.

BF=1: busy state

BF=0: ready for next instruction, command receivable.

The next instruction will not be accepted until BF is reset to 0.Check the BF status before the next write operation. At the same time, the value of the address counter (ACC) in binary AAAAAAA is read out. This address counter (ACC) is used by both CG-RAM and DD-RAM address and its value is determined by the previous instruction. The address counter are the same as for instructions set CG-RAM address and set DD-RAM address.

6.2.10 Write Data to CG or DD-RAM

DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0
			Data R	ead			

RS=1, R/W=0

This instruction writes 8-bit binary data (DB7 to DB0) from CG-RAM or DD-RAM.

The previous designation determines whether CG-RAM or DD-RAM is to be read.

Before entering this read instruction, either CG-RAM or DD-RAM address set instruction must be executed. If not executed, the first read data will be invalid. When serially executing read instructions, the next address data is normally read from the second read. The address set instructions need not be executed just before this read instruction when shifting the cursor shift instruction (when reading out DD-RAM). The operation of the cursor shift instruction is the same as the set DD-RAM address instruction.

After a read, the entry mode automatically increases or decreases the address by 1.

STANDARD	SPECIFICATION FOR APPROVAL	DOCUMENT NO.	REV.NO	PAGE
NAME	SPECIFICATION FOR AFFROVAL		00	21/22

Note: The address counter (ACC) is automatically incremented or decremented by 1 after the write instructions to CG-RAM or DD-RAM are executed. The RAM data selected by the ACC cannot be read out at this time even if read instructions are executed. Therefore, to correctly read data, execute either the address set instruction or cursor shift instruction (only with DD-RAM), then just before reading the desired data, execute the read instruction from the second time the read instruction is sent.

### 7.0 PERATING RECOMMENDATIONS

- 7.1 Avoid applying excessive shock or vibration beyond the specification for the VFD module.
- 7.2 Since VFDs are made of glass material, careful handling is required.
  i.e. Direct impact with hard material to the glass surface (especially exhaust tip) may crack the glass.
- 7.3 When mounting the VFD module to your system, leave a slight gap between the VFD glass and your front panel. The module should be mounted without stress to avoid flexing of the PCB.
- 7.4 Avoid plugging or unplugging the interface connection with the power on, otherwise it may cause the severe damage to input circuitry.
- 7.5 Slow starting power supply may cause non-operation because one chip Mico won't be reset.
- 7.6 Exceeding any of maximum ratings may cause the permanent damage.
- 7.7 Since the VFD modules contain high voltage source, careful handing is required during powered on.
- 7.8 When the power is turned off, the capacitor dose not discharge immediately. The high voltage applied to the VFD must not contact to the ICs. And the short-circuit of mounted components on PCB within 30 times the specified current consumption when the power is turned on.
- 7.9 The power supply must be capable of providing at least 3 times the rated current, because the surge current can be more than 3 times the specified current consumption when the power is turned on.
- 7.10 Avoid using the module where excessive noise interference is expected. Noise may affects the Interface signal and causes improper operation. And it is important to keep the length of the interface cable less than 50cm.
- 7.11 Since all VFD modules contain C-MOS ICs, anti-static handing procedures are always required.
- NOTE: Newhaven Display reserves the right to change or modify this spec or design without notice in order to improve the quality or design of this product.
